#### Abstract

Objectives: We conducted this study to determine the safety and evidence of effectiveness of Septimeb <sup>TM</sup> among patients with COVID-19. Materials and **methods:** A phase II clinical trial with Septimeb<sup>TM</sup> was implemented in Imam Khomeini Hospital as a before and after trial during May to October 2020. Considering the inclusion and exclusion criteria, 33 patients with COVID-19 were treated using Septimeb<sup>TM</sup>. The patients received the antiinflammatory drug 150 mg/10 ml/IV infusion Septimeb<sup>TM</sup> on the irst day and then 300 mg/20 ml/ IV infusion from the second day onwards for at least 2 days and up to 13 days based on the improvement of clinical symptoms and laboratory indings in addition to treatment which were selected according to the national protocol. The patients were then evaluated for the treatment efficacy and side effects. Adherence to treatment, clinical observations, and side effects were recorded before and after the treatment. **Results:** The herbal drug Septimeb<sup>TM</sup> was injected in phase two of a clinical trial on 33 patients with COVID-19 in Imam Khomeini hospital in Tehran as a before-and-after trial. The number of new cases admitted to the Intensive Care Unit (ICU) and the new need to NIV decreased compared to before treatment. Also, blood oxygen saturation and platelet count increased. Conversely, CRP, ESR, and ferritin levels decreased (P<0.05). Besides, Septimeb<sup>TM</sup> did not show any serious side effects except recurrent thrombophlebitis during the treatment. Conclusion: We found some evidence regarding the efficacy of this drug and its low amount of short term side effects. The investigators recommend conducting the third phase of the clinical trial.

Keywords: COVID-19; Septimeb<sup>TM</sup>; Clinical trial; ICU, NIV; Laboratory profile

# Introduction

On December 31, 2019, the first case of the novel coronavirus disease (COVID-19), caused by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2), was diagnosed in Wuhan, China. Due to the nature of the virus, the unknown gene sequence, and its effects, the disease was recognized as a crisis by the World Health Organization (WHO).

Clinical studies have been designed and implemented from the beginning of the spread to identify clinical, laboratory and

radiological symptoms of the disease, as well as therapeutic and preventive measures, and underlying factors. Due to the novelty of this virus and the absence of adequate information about the disease caused by this virus in humans, conducting epidemiological studies in

communities affected by the SARS-CoV-2 virus is necessary to make them prepared to limit its spread and to identify and treat the patients [1]. Over the past 23 months, all countries around the world have contracted the disease. The first confirmed case of the COVID-19 virus in Iran was reported in February 2020 in Qom. The registered number of infected people has been reported to be about 5,899,509 so far [2]. Because of the rapid spread of this disease, creating strategies to speed up the diagnosis of patients, isolating them from other patients to reduce the risk of disease transmission can be crucial [1]. Because there was no history of the disease, most treatments received were experimental and based on clinical evidence. These treatments have been done using corticosteroids, antiviral drugs, oxygen therapy, and methods of controlling infectious diseases. Besides, reviewing the results of antiviral drugs that are effective on other similar viruses can help establish treatment protocols in COVID-19 patients [3]. In Iran, the COVID-19 guideline for diagnosis and treatment of outpatient and inpatient services provided by the Ministry of Health and Medical Education (MOH and ME) is a resource for physicians to integrate into the selection of diagnostic and treatment methods for patients. However, the effectiveness of this guideline has not yet been determined and studies are needed to determine the treatment response of patients with COVID-19. The inflammatory response plays an important role in COVID-19, and inflammatory cytokine storm raises the severity of COVID-19. CRP is a non-specific acute-phase protein aroused by IL-6 in the liver and a sensitive biomarker of inflammation, infection, and tissue damage. Cytokines are produced by steroid hormones, neuropeptides, and bacterial components [4]. CRP expression level is usually low but rises rapidly and significantly during acute inflammatory responses. Study presented that high level of peripheral blood cytokine IL-6, CRP and the existence of hypertension were independent risk factors for measuring the severity of COVID-19. The risk model established upon IL-6, CRP and hypertension had the most predictability value in this study [5]. Study illustrated that the consideration of low lymphocyte counts and the serum levels of CRP, D-dimers, ferritin, cardiac troponin and IL-6, may be used in predicting the severity and fatality COVID-19 in the hospitalized patients [6]. In this experimental study, we tested the safety of Septimeb<sup>TM</sup> for treatment of COVID-19 in conjunction with national treatment protocol. Septimeb<sup>TM</sup>, an injectable anti-inflammatory drug, is an herbal medicine that combines Tanacetum vulgare (tansy), Rosa canina, Urtica dioica extracts plus selenium, flavonoids, and carotene to inhibit cytokine cascade through the regulation of TNF- $\alpha$ , interferon- $\gamma$  (IFN- $\gamma$ ) and IL-2. The drug is patented in Europe with the code WO/2007/087825 [7]. Septimeb<sup>TM</sup> is a condensed form of the drug IMODTM, which is an immunomodulation. It is an herbal drug and a stronger form of IMOD. This drug is the combination of the extract of dog rose, Utica device, Tanacetum vulgare, selenium, flavonoid, and carotenes [6,8]. Tan acetum vulgar has anti-inflammatory effects. Urtica dioca most probably prevents the maturation of myeloid dendritic cells and reduces T-cell responses. Experimental studies have shown that Septimeb<sup>TM</sup> can

regulate TNF-  $\alpha$ , IFN-  $\gamma$ , and IL-2. *In-vivo* and *In-vitro* studies have shown that IMOD<sup>TM</sup> can also have a favorable effect on type-1 diabetes and inflammatory bowel disease [8,9]. Since a few medicines or vaccines have been approved for the definitive treatment or preventive goals of COVID-19 disease, the researchers intended to evaluate the safety and evidences of efficacy of Septimeb<sup>TM</sup> injectable anti-inflammatory drugs in patients with COVID-19 in Iran in the second phase of a clinical trial. In case of adequate response to treatment and safety, the third phase of the clinical trial should be performed by considering the experimental and control groups and in a multicenter way.

## **Materials and Methods**

#### Study design and participants

On the first day, Septimeb<sup>TM</sup> 150 mg/10 ml/IV infusion and then from the second day onward Septimeb<sup>TM</sup> 300 mg/20 ml/IV infusion was given to the patients for at least 2 days and a maximum of 13 days based on improvement in clinical symptoms and signs, and laboratory profiles. Blindness did not exist in this study, and it was done as an open-label. Since the main purpose of the study in the second phase is to evaluate the safety of the drug, there was no control group. A total of 33 patients were enrolled in the study. Twenty-four people (72.7%) were not in the Intensive Care Unit (ICU) before the treatment and nine patients (27.3%) were hospitalized in the ICU from the beginning. Of the nine patients in the ICU, six patients were in ICU before treatment and three patients were transferred to the ICU on the first day of the intervention, following the onset of worsening clinical symptoms and signs prior to drug infusion.

#### Sample size

We used G-Power software to calculate the sample size and the sample size was 33.

**T tests:** Means: Difference between two dependent means (matched pairs)

Analysis: A priori: Compute required sample size

Input: Tail(s)=Two

Effect size dz=0.51

α err prob=0.05

Power (1- $\beta$  err prob)=0.80

**Output:** Noncentrality parameter  $\delta$ =2.9297269

Critical t=2.0369333

Df=32

Total sample size=33

Actual power=0.8107962

#### **Eligibility criteria**

**Inclusion criteria**: We included the hospitalized patients in Imam Khomeini Hospital Complex of Tehran, which were adult ( $\geq$  18 years old, both genders), confirmed COVID-19 with PCR test, and with moderate or severe diseases after filling written consent form during May 2020 to October 2020. Patients' hospitalization indications were based on management national protocol of COVID-19. All patients took standard care of COVID-19 based on the national protocol (O<sub>2</sub> support, hydration, Dexamethasone 8 mg/IV/ daily, Enoxaparin 1 mg/Kg/daily, Remdesivir 200 mg/stat and 100 mg/daily for 4 days and Famotidine 40 mg daily).

**Exclusion criteria:** Children, pregnant women, the patients under mechanical ventilation, cases with history of anaphylactic reaction, Chronic Kidney Diseases (CKD), Chronic Heart Failure (CHF), chronic hepatitis, vacuities, malignant diseases, HIV and patients with negative SARS-CoV-2 RT PCR were excluded. Moreover, patients who underwent convalescent plasma infusion and/or received tocilizumab were not included in the study.

#### **Measurements**

Septimeb<sup>TM</sup> drug included a 10 ml via of 150 mg active ingredients content that was diluted in 500 ml dextrose water 5% and was given to the patients once within 1.5 hours in the form of infusion. In the absence of side effects, especially hypersensitivity reactions, 20 ml containing 300 mg active ingredients was diluted in 500 ml dextrose water 5%. The Septimeb<sup>TM</sup> drug was given to the patients for 2 to 13 days, depending on the clinical symptoms of each patient. The drug was discontinued after improvement of clinical symptoms (with doctor's discretion). The information about gender, age, underlying diseases, symptoms, signs, treatment duration, and hospitalization duration of the related questionnaire was recorded and kept confidential. Primary outcome was length of hospitalization (general ward/ICU days), the potential side effects (during three months of intervention) and mortality rate (after 3 month of intervention). Improving (during 14 days of intervention) symptoms and changes in inflammatory markers were secondary outcomes. All patients were daily checked in terms of improving or incidence of clinical symptoms and signs, recorded length of admission, laboratory indexes, and need for hospitalization in ICU. After improvement of clinical symptoms with a doctor's discretion, the patients' medications were stopped. Blood samples for checking changes in inflammatory markers were collected before and immediately after stopping the drug. Potential side effects and mortality rate were followed up within and after three months of the start of the intervention.

#### **Ethical considerations**

The study was approved by the Tehran University of Medical Science (TUMS) ethical committee. After examination of entry and exit criteria and also obtaining informed written consent, patients were treated. Participation in this project has been voluntary, and patients had to volunteer themselves for the treatment. Patients were allowed to refuse to cooperate with the study and follow-up whenever they wanted. However, in cases where patients did not refer for follow-up treatment and periodic evaluations, the research team followed up based on the patient's address and asked the reasons for not referring. If the non-referral was for reasons other than dissatisfaction and desire, efforts were made to eliminate it as much as possible and the treatment process continued. All patients' information was considered strictly confidential and was not disclosed to the patient or his/her legal representative. For this purpose, patients' records were kept in a safe place.

#### **Statistical analysis**

All collected data were entered into a computer and analyzed by software package SPSS, version 26 (IBM North America, New York, NY, USA). Quantitative findings were reported as mean and standard deviation and qualitative findings were reported into frequency and percentage. Parametric and nonparametric tests were used to compare before and after based on normality test. Considering the result of the Kolmogorov-Smirnov test, the Paired Samples T-Test, and the McNemar test were used to compare the difference before and after Septimeb<sup>TM</sup> administration.

#### **Results**

#### **Descriptive findings**

During this study, 92 patients were evaluated and 45 patients (48.9%) became candidates for participating, but finally a total of 33 patients (73.3%) included. Also, 3 persons (9.1%) died during the study. About 79% of participants were male and 21% were female. The mean and median ages were 53.7 and 54 years (18-79). The duration of treatment varied from 2 days to 13 days with mean of 5.9 days. Besides, the maximum hospitalization period was 42 days and its minimum was 6 days by mean  $\pm$  SD of  $16.0 \pm 7.95$ . The most common clinical signs before starting treatment include dyspnea (93.8%), fever (65.5%), and Gastrointestinal (37.5%). Table 1 shows the demographic characteristics and clinical symptoms and signs of the patients studied.

#### Safety and adverse events

Eleven patients (33.3%) were treated less than 5 days by Septimeb<sup>TM</sup>. The mean oxygen was 79.9 before the treatment and 91.6 after the treatment. Before treatment, six patients (18.2%) were under intensive care at the ICU and 15 patients (48.4%) were under Non-Invasive Ventilation (NIV). During treatment, 10 patients (30.3%) underwent NIV and in the first day of intervention, three of those who were under NIV, transferred to the ICU. After treatment, two patients (6%) were under intensive care at the ICU; one patient was in the ICU before starting treatment, and one patient was in the ICU during treatment. At the end of treatment, none of the patients had fever; two patients (6%) had dyspnea two patients (6%) remained under NIV. Examination of the results within 3 months in 33 patients has shown that the side effects of this drug were recurrent thrombophlebitis among seven patients (21.2%) which due to this complication, treatment with this drug was discontinued for the patients. Also, no side effects were observed on laboratory markers in any of the patients. There were no deaths three months after treatment (Table 1).

#### **Evidence of the effectiveness**

The patients all adhered to injectable Septimeb<sup>TM</sup> (100%). About the evidence of the effectiveness of this drug among 33 patients with COVID-19 on ICU hospitalization, need for NIV and laboratory findings, analysis of results with McNamara test showed that the number of ICU hospitalization (P=0.039) and new need of NIV (P<0.001) was significantly reduced after treatment with Septimeb<sup>TM</sup>.

Also, T-test results showed an increase in blood oxygen saturation (P<0.001), an increase in platelet count (P=0.03), a decrease in CRP (P<0.001), a decrease in the amount of ESR

(P=0.001), and ferritin (P=0.009) compared to before Septimeb<sup>TM</sup> treatment. Table 2 summarizes the status of these 33 patients before and after the treatment.

Table 2: Laboratory finding of patients with COVID-19 before and after treatment, imam khomeini hospital, Tehran, Iran.					
Variable	Before Treatment	After Treatment	P-value		
	Mean ± SD	Mean ± SD			
ICU, n (%)	9 (29.0)	2 (6.5)	0.039*

Lactate Dehydrogenase (LDH)	1094.20 ± 621.57	984.00 ± 540.90	0.5		

# Discussion

It was found that by testing Septimeb<sup>TM</sup> drug on 33 patients with COVID-19 for at least 2 days and a maximum of 13 days, the rate of new ICU hospitalization and a new need for NIV reduced compared to before the treatment. Also, blood oxygen saturation increased and there was no death after three months of intervention. This finding was in line with the findings they declared that Septimeb<sup>TM</sup> has positive effects on mortality rates in severe sepsis and showed that improved tissue oxygenation could be a reason for Septimeb's effect on reducing mortality rates [10]. Showed that lactate and cytokine production in sepsis was related to organ failure [11]. Another study has shown that serum lactate, dependent on organ failure and shock, is related to mortality rates in severe sepsis. Lactate is an unreliable indicator of tissue hypoxia in sepsis [8]. In this investigation, lactate levels were significantly lower in the Septimeb<sup>TM</sup> group at the end of the intervention compared to the control group. Therefore, improving tissue oxygenation can be a possible mechanism in reducing sepsis mortality after drug intervention with Septimeb<sup>TM</sup>. At the end of treatment, the results of comparison of laboratory samples and inflammatory factors showed that platelet count increased, and CRP, ESR, and ferritin decreased (p<0.05). These changes also improved patients' clinical symptoms and signs. Results of studies showed that IMOD<sup>TM</sup> is safe and has no allergic and mutagenic ability. Most importantly, IMOD<sup>TM</sup> potential effects in HIV positive patients on reducing the level of TNF- $\alpha$  and IL-2 has been represented [3]. In this study, the CRP level after the treatment with Septimeb<sup>TM</sup> was very low. Septimeb<sup>TM</sup> seems to reduce inflammatory factors, but it is not noticeable due to the low number of patients and short follow-up period [12,13]. The evaluation of the results of this drug on 33 patients demonstrated that this drug has few side effects including thrombophlebitis, which is easily treatable, and no serious side effects were observed in total. This is notable because other existing treatments have many side effects compared to Septimeb<sup>TM</sup>. Thus, the Septimeb<sup>TM</sup> drug has far fewer side effects than many existing medicines. Also, this drug was effective in the patient's laboratory profiles. In addition, during the intervention, unstable and anaphylactic hemodynamic responses were not observed. Consequently, due to the significant effect of this herbal drug on disease treatment and on the level of lactate, the sequential organ failure assessment (SOFA), and the Glasgow coma scale (which are indicators of recovery in patients with sepsis), the use of Septimeb<sup>TM</sup> with standard treatment can be recommended [7]. Septimeb<sup>TM</sup> may have a significant impact on reducing mortality rates, and if the follow-up period was higher, better results would have been achieved [13,14]. Also, Septimeb<sup>TM</sup> may have a substantial impact on reducing hospital costs, because, it is herbal medicine and produced domestically. In phase 1 clinical trial study on Septimeb<sup>TM</sup> safety assessment, male patients with HIV infection with CD<sub>4</sub> levels above 200 cells/mm<sup>3</sup> in four cohorts of 3 people showed that up to 10 ml per day was tolerable for 4 weeks. Due to the lack of serious side effects related to Dose Limiting Toxicity (DLT) and easy tolerance of the doses received (5,6,7 and 8 ml) by these 12 patients with HIV infection, it seems that patients can tolerate up to 8 ml easily. In addition, by

comparing CD4 levels before and after receiving the drug and observing a significant increase in CD<sub>4</sub> in some of these patients, it can be found that this drug can significantly increase CD<sub>4</sub> within two weeks [7]. Which has been registered as a phase 1 clinical trial study of Septimeb<sup>TM</sup>, was aimed exclusively at accessing the maximum tolerable dose of the drug in human samples. The maximum dose of this study can be used to select therapeutic doses for other patients [8]. findings have pretty much the same result as our and the mentioned study. They have tested it on patients with sepsis and found that Septimeb<sup>TM</sup> illustrates positive effects on survival of patients with severe sepsis, considering the withdrawal of activated protein C. Follow-up of people with COVID-19 is particularly difficult in clinical trial studies. For various reasons, they may discontinue treatment, which should be encouraged by repeated follow-ups and incentives to take medication according to the doctor's instructions. Our findings are subject to several limitations. The number of participants in this study was low and the possible random error was not completely removable. The main limitation of the study is the absence of a control group, which in the design of the third phase of the study; this limitation has been removed by having a control group. The aim of this study was to observe the safety and efficacy of Septimeb<sup>TM</sup> in COVID-19 moderate and severe patients and to collect relevant data to design third phase to compare the case group with the control group.

#### Conclusion

It seems that this drug has a few side effects, at least in the short term. Also, at this stage of the research, evidence of the effectiveness of this drug has been obtained that it is needed to further investigate the formulation of oral form and possibly the preparation and production of a new oral form because the injectable form has had significant effects on increasing blood oxygen saturation and platelet count among patients with COVID-19.
